

# Physical Conditions and Star Formation in Cluster-Forming Molecular Clumps

*Peter Barnes*  
*University of Florida*  
*with Billy Schap, Tony Ordonez (UF) and Adam Ginsburg (ESO)*

*AASTCS4: Workshop on Dense Cores, Monterey CA, 27-30 July 2014*

2/15

## The Problem of Massive SF

- *Milky Way is **ideal local calibrator** for tracers of massive star/cluster formation seen in other galaxies and to high redshift, but...*
- ***Systematic MW surveys** of massive star formation/cluster formation **difficult** because of rarity => large distances, also short timescales, complex phenomenology*
- *Typically plagued with selection effects, small sample size, uniformity, limited fields of view*
- *Need uniform, wide sky coverage, high resolution, AND multiple wavelengths*
- *Started **CHaMP** in 2002: new results address these issues...*

# What is CHaMP?

## *The Galactic Census of High- and Medium-mass Protostars*

- *Based on Nanten maps (PIs Yonekura, Fukui)*
- *An **unbiased** multi-wavelength Galactic Plane survey ( $20^\circ \times 6^\circ$ ) of a complete population (303) of massive, dense, parsec-scale molecular clumps*
- *At 3mm with Mopra (2004–2012): simultaneous maps of MANY molecular tracers*
- *In NIR+MIR (2007–2013) with AAT (Stuart Ryder), CTIO (Krista Romita), Warm Spitzer*

## 1. CHaMP in HCO<sup>+</sup>

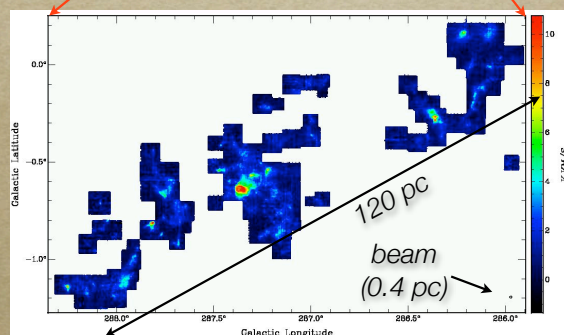

*Barnes et al 2011  
ApJS 196 12*

**ONLINE:**  
All data cubes,  
moment maps  
(integrated intensity,  
velocity field, linewidth),  
and data tables of clump  
properties:

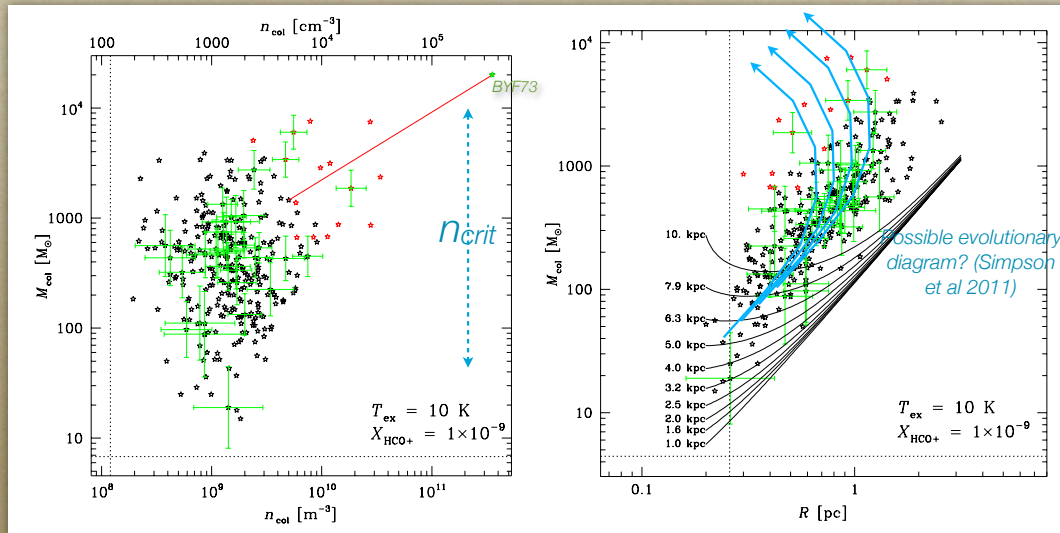

[www.astro.ufl.edu/champ](http://www.astro.ufl.edu/champ)

*η Carinae GMC*

# HCO<sup>+</sup> results

*mass-density*

*mass-radius*

## HCO<sup>+</sup> summary

- **Vast population** of massive ( $10\text{--}10^4 M_{\odot}$ ), dense ( $3 \times 10^{2-4} \text{ cm}^{-3}$ ), pressure-bounded, but **subthermally-excited** clumps — predicted by Narayanan et al 2008. Consistent with emerging view of KS laws being physically based on amount of **dense gas** present, not just all gas
- Most of these seem (relatively) quiescent in their massive SF activity
- Implies a long, quiescent lifetime for clumps (50 – 100 Myr) **before** massive SF turns on
- Can reconcile “short-” and “long-lived” views of massive star-forming clumps

## 2. CHaMP in IR

- AAT+CTIO **broadband JHK** imaging & photometry
  - Deep Warm Spitzer IRAC **Band 1+2** mosaics of 90% of HCO<sup>+</sup> clumps: imaging & photometry
  - GLIMPSE **Band 3+4** photometry
- } Large-scale near- & mid-IR embedded cluster demographics, *in prep.*
- **Narrowband NIR** results for 20% of clumps (*Barnes et al 2013 MNRAS 432 2231*):
    - line-free K-continuum
    - H<sub>2</sub> v=1-0 S(1)
    - H<sub>2</sub> v=2-1 S(1)
    - Brackett-γ
- } Use line-free K-cont to make continuum-subtracted line images

## Compare mm and NIR-narrowband

**AAT images:**

**H<sub>2</sub> v=1-0 S(1)**

**H<sub>2</sub> v=2-1 S(1)**

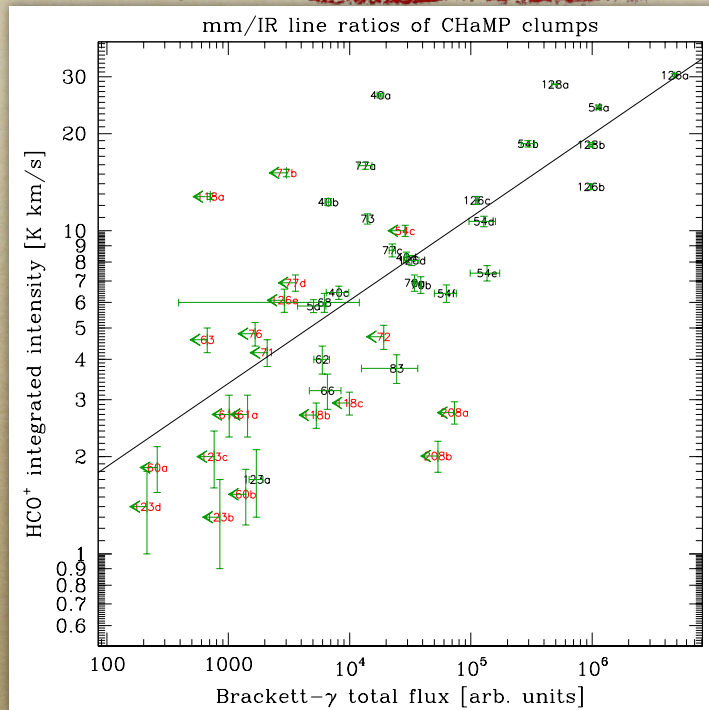

**Brγ**

**Mopra contours:**

**N<sub>2</sub>H<sup>+</sup>**

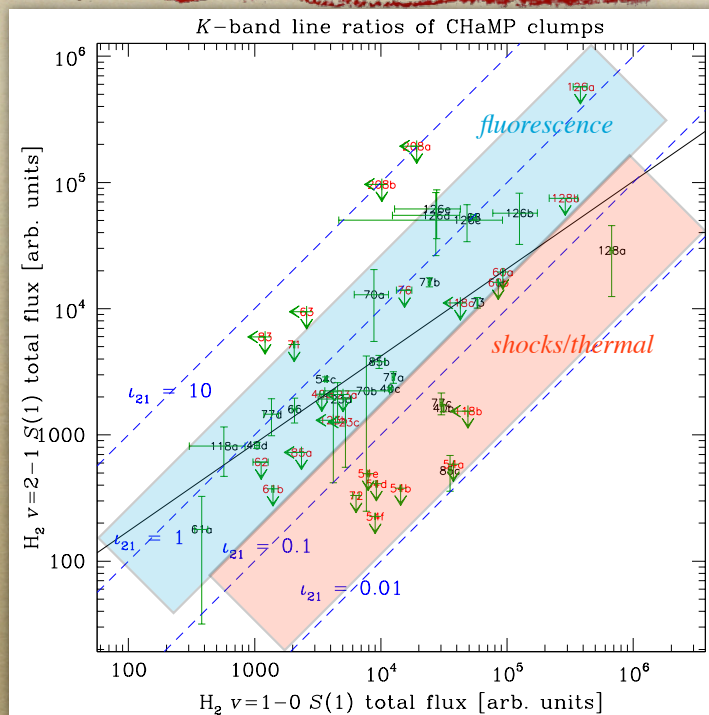

# New signposts

- $\text{HCO}^+$  (brightness, not linewidth!) and  $\text{Br}\gamma$  are **signposting the same thing**: how can this be?
- $\text{N}_2\text{H}^+$  and  $\text{H}_2$  lines are **NOT** correlated with each other, nor with  $\text{HCO}^+$  or  $\text{Br}\gamma$

# New signposts

- However,  $\text{H}_2$  line emission is dominated by **fluorescence**, not shocks
- Consistent with observed morphology (mostly around HII regions, not many outflows)

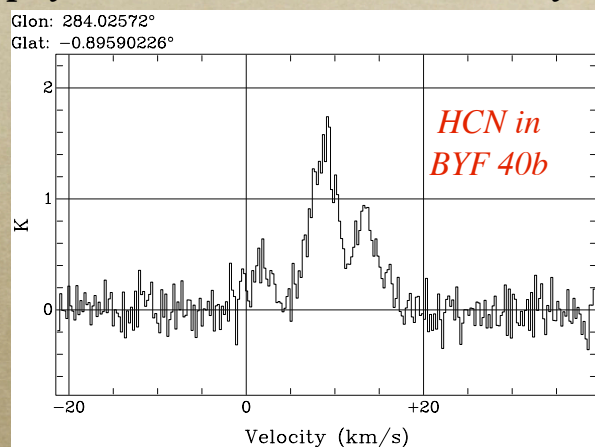

# NIR-narrowband summary

- $\text{HCO}^+/\text{N}_2\text{H}^+$  ratio seems correlated with ionising flux from a clump's embedded MYSO population (cf Meyer & Turner 2012 results for Maffei 2)
- $\text{HCO}^+$ ,  $\text{Br}\gamma$ , and  $\text{H}_2$  seem to signify a late-stage surge in massive star/cluster formation and photon-driven evolution
- Supports picture of long-lived clumps terminated by MSF
- $\text{N}_2\text{H}^+$  seems a better tracer of pre-cluster cold gas
- "Dense gas" tracers do not trace a homogeneous population of clouds!!!

## 3. Hyperfine CHaMP

- Maps of hyperfine-split lines of  $\text{HCN}$  and  $\text{N}_2\text{H}^+$  can produce spatially-resolved maps of physical conditions and chemistry
- Analysis of hyperfine physics can be compared in detail with  $\text{HCO}^+$  and other species' simple  $J$ -line abundances and kinematics
- Tools of choice: *pyspeckit* + *Miriad* + *shellscript*

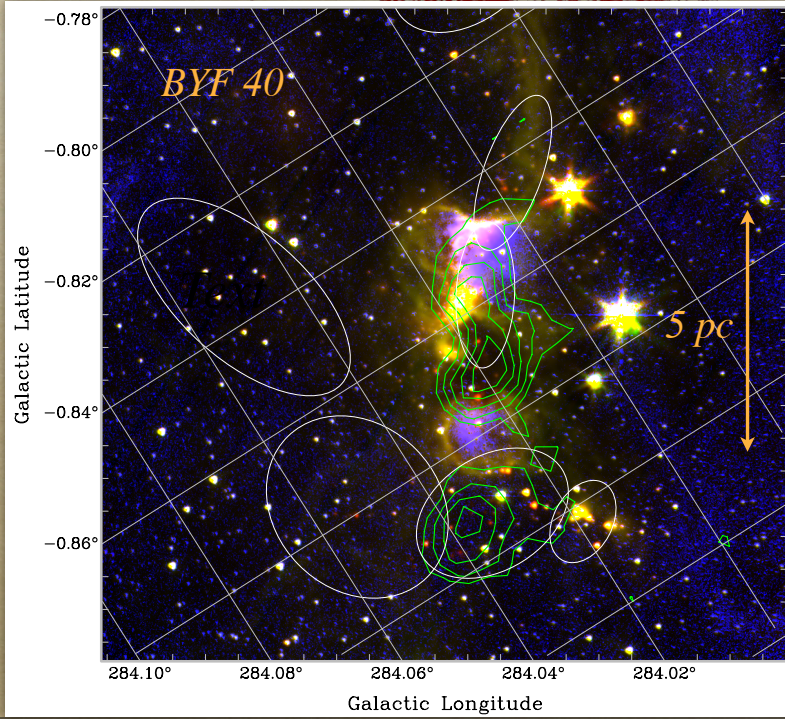

- Start with  $\text{HCN}$  in one region of 7 clumps:  
BYF 40  $d \sim 6.6$  kpc  $M \sim 2000\text{--}7000 M_\odot/\text{clump}$

# NIR + MIR + 3mm

*images:*  
 DWS: band 2  
 DWS: band 1  
 AAT: Bry

*contours:*  
 $N_2H^+$

*ellipses:*  
 $HCO^+$  clumps'  
 HPW

# NIR + MIR + 3mm

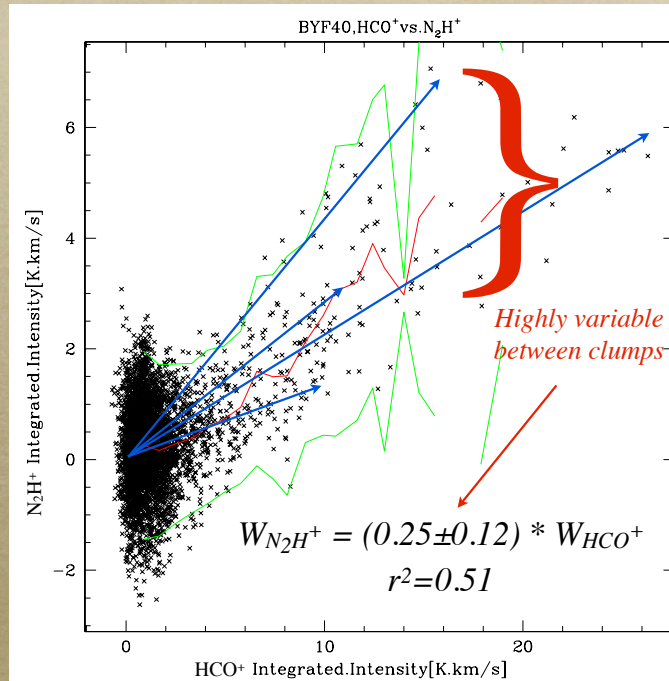

*images:*  
 $N_2H^+$   
 $HCN$   
 $HCO^+$

*ellipses:*  
 $HCO^+$  clumps'  
 HPW

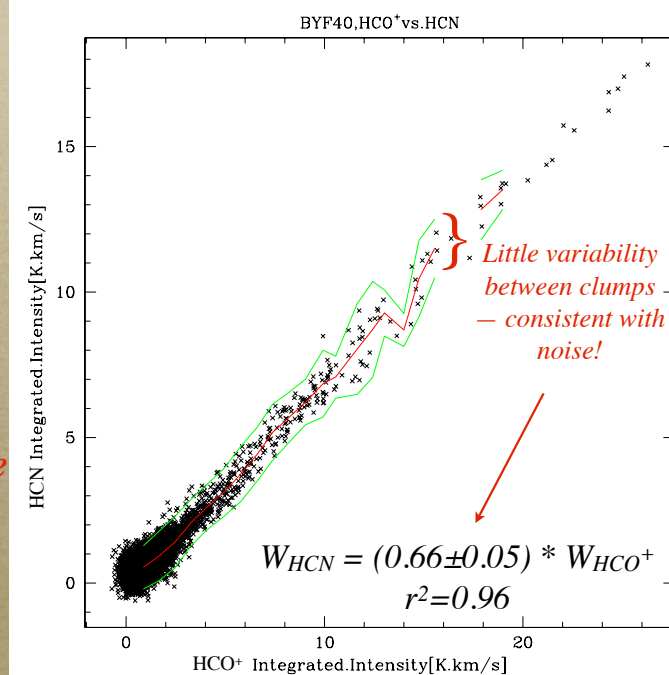

## “Dense gas” tracers

- *CHaMP clumps show similar 3mm morphology & distribution among many molecular tracers, e.g.  $\text{HCO}^+$ ,  $\text{HCN}$ ,  $^{13}\text{CO}$*
- $\text{N}_2\text{H}^+$  is *very different* to these (probably due to CO freeze-out and desorption, producing and destroying  $\text{N}_2\text{H}^+$ )

## “Dense gas” tracers

- So  $\text{N}_2\text{H}^+$  line flux is temperature and/or ionisation-sensitive
- BUT!**
- $\text{HCN}$  and  $\text{HCO}^+$  (at least) must share very similar chemistry!
  - So this ratio is temperature-*IN*sensitive
  - But from  $\text{Br}\gamma$ ,  $\text{HCO}^+$  and  $\text{HCN}$  line flux are ionisation-sensitive

# What about column densities?

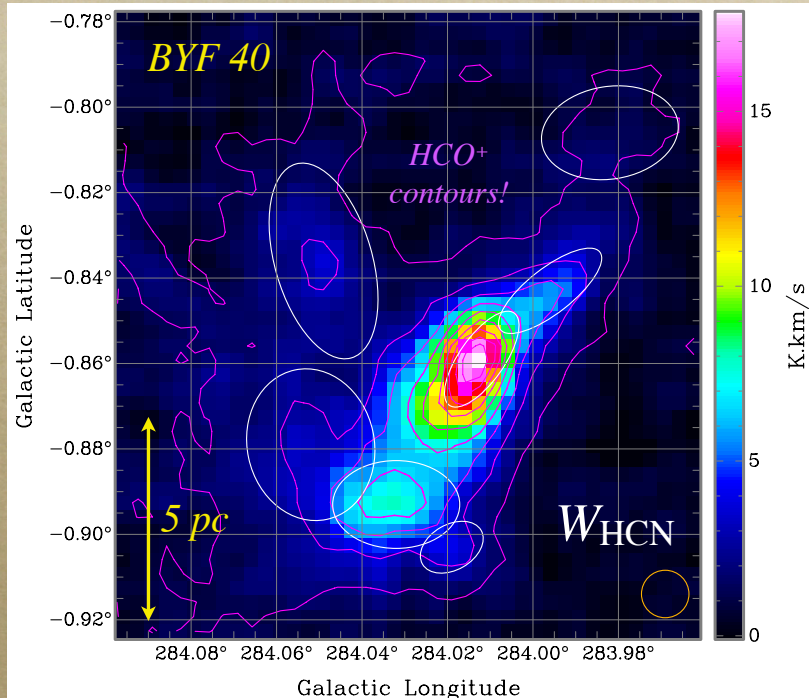

- *Simple radiative transfer analysis:*

$$N_{\text{HCN}} = 9.0 \times 10^{15} \text{ m}^{-2} \frac{Q(T_{\text{ex}}) e^{E_{\text{up}}/kT_{\text{ex}}}}{1 - e^{-h\nu/kT_{\text{ex}}}} \int \tau dV_{\text{km/s}}$$

- **Normally** use  $J_b = (J_{\text{ex}} - J_{\text{bkgd}})(1 - e^{-\tau})$  and  $\tau \ll 1$  to estimate  $\tau \sim J_b/J_{\text{ex}} \sim T_b/T_{\text{ex}}$ , and obtain  $N$  from  $W = \int T_b dV$  and  $T_{\text{ex}}$  from other methods (sometimes assumed)
- **Hyperfine-split lines** give  $\tau$  and  $T_{\text{ex}}$  **directly** (also  $V_0, \sigma_V$ ) assuming only that HF ratios are in LTE: gives  $N$  without further assumptions or cross-calibration uncertainties
- Then get mass from abundance, or vice versa

# Start with HCN data cube

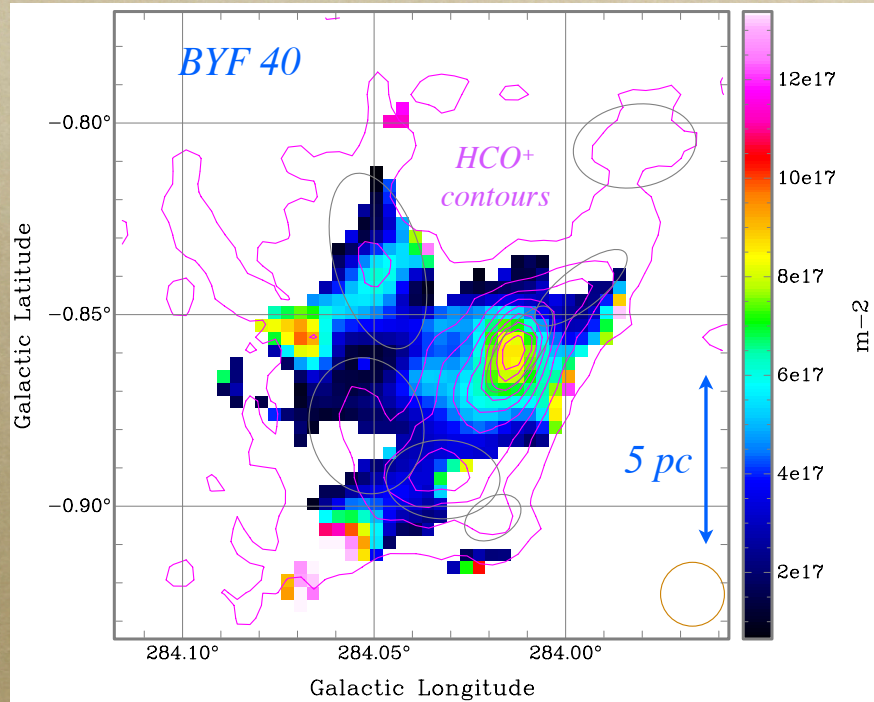

Use *pyspeckit*/  
*Miriad*/  
*shellscript* to  
convert full  
hyperfine  
spectrum to  
 $N_{\text{HCN}}$ , pixel by  
pixel

# Map of $N_{\text{HCN}}$

$\pi/e$

*This looks different!  
"Flatter" than  $W_{\text{HCN}}$*

# HCN hyperfine results

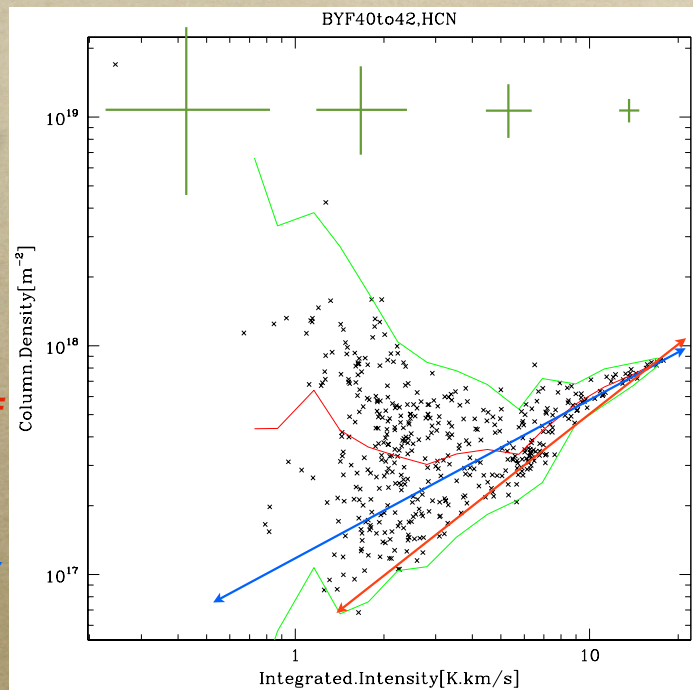

$i \pm \sum t$

- *Something unexpected is happening at low  $W$ !*

*Normal method when we don't know  $\tau$ ,  $T_{\text{ex}}$ : use  $W_{\text{HCN}}$  to estimate  $N_{\text{HCN}}$*

- *Linear relation:  $N_{\text{HCN}} = (5 \times 10^{16} \text{ m}^{-2}) * W_{\text{K.km/s}}$*

- *Power law:  $N_{\text{HCN}} = (1.2 \times 10^{17} \text{ m}^{-2}) * W_{\text{K.km/s}}^{0.7}$*

# HCN hyperfine results

- Convert to mass column assuming  $X_{\text{HCN}} = 10^{-9}$  (same as  $X_{\text{HCO}^+}$ ):  $\Sigma(M) = 24,000$  or  $37,000 M_{\odot}$
- BUT we can measure  $N_{\text{HCN}}$  in each pixel **without** assuming a conversion from  $W$ , and sum these to get a total (mass) column: actual  $M_{\text{tot}} = 57,000 M_{\odot}$  !
- This is  $\sim 2\times$  naïve “ $W$  methods” because of **large areas with low  $W$ , low  $T_{\text{ex}}$ , high  $\tau$ , and yet high  $N$** . (Note that this is an overall result: some clumps are much more massive, some actually less, than with  $W$  methods.)
- cf. mass of these clumps as measured by  $\text{HCO}^+ \sim 16,000 M_{\odot}$ . But masses must be the same  $\Rightarrow X_{\text{HCN}} \sim 4 * X_{\text{HCO}^+}$

# Applications & Implications

- Can use this information to obtain **self-consistent** relative abundance maps between  $\text{HCO}^+$  and  $\text{HCN}$  (and other species): strong constraints on chemical models
- But more significantly....
- **Mass estimates that rely on simple  $W$  scalings may substantially underestimate the gas mass in these clumps!**
- Implies there is a lot more “dense” gas in massive clumps not engaged in massive star formation: extends  $\text{HCO}^+$  results
- **Consequences** for clump stability, calibration of K-S relations, among many other things....

## Next steps

- *Need to apply these methods to HCN maps of **the rest of the 303 CHaMP clumps***
- *Derive  $T_{ex}$  and **relative abundance maps**; new mass estimates?*
- *Relate to NIR+MIR data*
- *Make results **publicly available** for modellers on CHaMP web pages: FITS files of data, derived quantities; machine-readable tables+catalogues*
- *Extend analysis to  $N_2H^+$  data, other species*

## Thank you
